

# The poisson process

---

- Draw the transition graph for the poisson process. How many states does this markov chain have.
- Write out the jump rate matrix for the poisson process.
- Explain the three assumptions that we make when we model a counting process using a poisson process.
- Use the kolmogorov equation to derive a differential equation involving  $\frac{dp_{03}(t)}{dt}$  for the Poisson process.

# The poisson process

---

- Show in your notes why the fact that  $\frac{dP_{00}(t)}{dt} = -\lambda t$  together with the fact that  $P_{00}(t) = 0$  implies that  $P_{00}(t) = e^{-\lambda t}$ .
- Show that  $\frac{d[e^{\lambda t} P_{01}(t)]}{dt} = e^{\lambda t} \frac{dP_{01}(t)}{dt} + \lambda e^{\lambda t} P_{01}(t)$  using the product rule and explain how this fact is used when we solve a differential equation using an integrating factor.
- Use the method of integrating factors to derive an expression for  $P_{03}(t)$  starting from the differential equation that you wrote down in the third of these questions.
- Give the expression for  $P_{0n}(t)$  that is derived in the video for the poisson process.
